Abstract

Der steigende Einsatz synthetischer Nanomaterialien erfordert zuverlässige Vorhersagen über Auswirkungen von Nanopartikeln auf die Umwelt. In dieser Arbeit “Energy Levels and Dissolution: Two Predictors of Metal Oxide Nano-Bio Interactions” werden mit (1) den Energieniveaus der Bandstruktur und (2) dem Auflösungsverhalten von Metalloxid-Nanopartikeln in biologischen Umgebungen zwei wesentliche Prädiktoren für deren Toxizität untersucht. Die präzise Quantifizierung sowie die gezielte Anpassung der Partikeleigenschaften durch das Einbringen von Fremdatomen stehen dabei im Fokus der Arbeit.

Überschneiden sich die in Metalloxid-Nanopartikeln verfügbaren Energieniveaus wie Leitungs- und Valenzband mit denen der biologischen Umgebung, können zellschädigende Reaktionen ausgelöst werden. Zur Quantifizierung der Energieniveaus unter umweltnahen Versuchsbedingungen wurde ein dreistufiges Verfahren zur Herstellung von porösen Nanopartikelektroden entwickelt, welches eine elektrochemische Charakterisierung der Nanopartikel in wässrigen Umgebungen ermöglicht. Im ersten Prozessschritt werden die Nanopartikel mit bereits etablierten Verfahren auf ein elektrisch leitfähiges Elektrodensubstrat transferiert. Um störende Beiträge des Elektrodensubstrates auszuschließen werden die Poren der Nanopartikelschicht im zweiten Prozessschritt mit einem Monomer aufgefüllt, welches anschließend polymerisiert wird. Der dritte Prozessschritt ist eine Plasmabehandlung der Nanopartikel-Polymer Oberfläche, um den für die Messung benötigten Kontakt zwischen Nanopartikeln und Umgebung sicherzustellen. Mit diesem Verfahren wurde das Flachbandpotenzial von fünf Metalloxid-Nanomaterialien präzise bestimmt, welches in direktem Zusammenhang zu deren Energieniveaus steht. In Relation zur biologischen Umgebung kann aus den Messungen die potentielle Toxizität der Nanopartikel vorhergesagt werden.

Lösen sich Nanomaterialien in biologischen Umgebungen auf, spielen die gelösten Stoffe eine größere Rolle als die Energieniveaus der Materialien. Werden schädliche Stoffe freigesetzt, bestimmt die Auflösungskinetik in Relation zu den regulatorischen Mechanismen der Zelle die Auswirkungen auf den Organismus. Durch ihre starke Auflösung in biologischen Umgebungen sind Kupferoxid- und Zinkoxid-Nanopartikel zwei Materialien mit einer hohen Toxizität, sowohl in Zell- als auch in Tierexper-

imenten. In beiden Fällen konnte durch die Einbringung von Eisen (Dotierung) während der Partikelsynthese eine signifikante Reduzierung der Auflösung und damit der Toxizität erzielt werden. Im Rahmen dieser Arbeit wurde die Auflösungskinetik von Kupferoxid-Nanopartikeln in abiotischen Modellmedien mittels Absorptionsspektroskopie untersucht, um Unterschiede zwischen reinen und dotierten Materialien zu identifizieren. Im Gegensatz zur schnellen Freisetzung von reinem Kupferoxid, wurde bei eisendotiertem Kupferoxid ein zweistufiger Auflösungsprozess beobachtet. Die Partikelcharakterisierung vor und nach partieller Auflösung zeigt strukturelle Veränderungen der Partikel auf und ist die Basis für das in dieser Arbeit entwickelte Kinetikmodell. Mit Hilfe des Modells konnten Struktur-Freisetzung-Beziehungen aufgestellt und die wesentlichen Parameter der Auflösung identifiziert werden.

Durch die modellgestützte Anpassung der Auflösungskinetik von Kupferoxid-Nanopartikeln an die biologische Umgebung konnte die Toxizität in der Nanomedizin gezielt eingesetzt werden um Krebszellen anzugreifen, ohne dabei gesunde Zellen zu beeinträchtigen. In Kombination mit einer Immuntherapie verschwanden Tumore in der durchgeführten *in vivo* Studie vollständig. Auch dort, wo die konventionelle Chemotherapie durch Resistenzbildung versagt, ist der Ansatz mit Nanopartikeln erfolgsversprechend.

Abstract (English)

The increasing use of synthetic nanomaterials requires reliable predictions of the environmental impact of nanoparticles. In this thesis, 'Energy Levels and Dissolution: Two Predictors of Metal Oxide Nano-Bio Interactions', two key predictors of the toxicity of metal oxide nanoparticles are investigated: (1) the energy levels of the electronic band structure and (2) the dissolution behavior. The precise quantification and the specific adaptation of the particle properties through incorporation of foreign atoms are the focus of this thesis.

If the energy levels available in metal oxide nanoparticles, such as the conduction and valence band, overlap with those of the biological environment, cell-damaging reactions can be triggered. For the quantification of the energy levels under environmental experimental conditions, a three-step process for the production of porous nanoparticle electrodes was developed, which enables the electrochemical characterization of nanoparticles in aqueous environments. In the first process step, the nanoparticles are transferred to an electrically conductive electrode substrate using established methods. To prevent any disruptive contribution by the electrode substrate, the pores of the nanoparticle layer are filled with a monomer in the second process step, which is polymerized subsequently. The third process step is a plasma treatment of the nanoparticle-polymer electrode surface to ensure the contact between nanoparticles and the environment, as required for the measurement. With this method the flat band potential of five metal oxide nanomaterials was precisely determined, which is directly related to their energy levels. In relation to the biological environment, the potential hazard of the nanoparticles can be predicted from the measurements.

If nanomaterials dissolve in biological environments, the species which are released play a more important role than the energy levels of the materials. If toxic species are released, the dissolution kinetics in relation to the regulatory mechanisms of the cell determine the fate. Due to their strong dissolution in biological environments, copper oxide and zinc oxide nanoparticles are materials with a high toxicity in cell and animal studies. In both cases, the incorporation of iron (doping) during particle synthesis has led to a significant reduction in dissolution and thus toxicity. In this thesis, the dissolution kinetics of copper oxide nanoparticles in abiotic model

media were investigated by absorption spectroscopy to identify differences between pure and doped materials. In contrast to the rapid release of pure copper oxide, a two-step dissolution process was observed for iron-doped copper oxide. Particle characterization before and after partial dissolution reveals structural changes of the particles and is the basis for the kinetic model developed in this thesis. With the help of the model, structure-release relationships were established and the essential parameters of the dissolution were identified.

Through the model-based modification of the copper oxide dissolution kinetics to the biological environment, the toxicity was used in nanomedicine to specifically attack cancer cells without affecting healthy cells. In combination with immunotherapy, tumors disappeared completely in the *in vivo* study. Even where conventional chemotherapy failed due to the development of drug resistances, the approach with nanoparticles was successful.

A theory is something nobody believes, except the person who made it. An experiment is something everybody believes, except the person who made it.

A. Einstein

Preface

The results shown in this thesis were all obtained during my time as a PhD student at the Faculty of Production Engineering of the University of Bremen. During this time, from January 2015 until April 2020, Prof. Dr.-Ing. habil. Lutz Mädler supervised me. Main results are published as follows:

1. **H. Naatz**, Lin, S., Li, R., Jiang, W., Ji, Z., Chang, C. H., Köser, J., Thöming, J., Xia, T., Nel, A. E., Mädler, L. & Pokhrel, S. Acknowledgement

Mein besonderer Dank gilt Herrn Prof. Lutz Mädler, der mich während meiner Doktorarbeit und Zeit an der Universität Bremen und am Leibniz Institut für Werkstofforientierte Technologien - IWT stets an den richtigen Stellen unterstützt und motiviert hat. Mit seinem mir entgegengebrachten Vertrauen war es möglich, diesen Weg zu gehen und die Dissertation in der jetzigen Form fertigzustellen.

Herrn Prof. Hartmut Wiggers danke ich für die Bereitschaft, als Gutachter für diese Arbeit zur Verfügung zu stehen.

Ebenso bedanke ich mich bei Prof. Fabio La Mantia, Prof. Andreas Hartwig, Prof. Jorg Thöming und Dr. Johannes Birkenstock für die gemeinsame Arbeit und die Diskussion meiner Ergebnisse, die mir an vielen Stellen sehr geholfen hat sowie bei Stefaan Soenen und Bela Manshian von der KU Leuven für die Kooperation und Bereitstellung ihrer Ergebnisse.

Ich bedanke mich bei meinen Kolleginnen und Kollegen für eine tolle Zeit an der Universität Bremen und am Leibniz Institut für Werkstofforientierte Technologien - IWT. Ein besonderer Dank geht vor allem an Valentin, mit dem ich mir lange Zeit ein Büro teilen durfte und ohne den ich immernoch Filterkaffee trinken würde, an Suman, der mich mit seiner optimistischen Art jederzeit unterstützt hat, an Ron für die gemeinsame Arbeit und die aufwendig präparierten Elektroden sowie an Eric und Malte für das Feedback zu meiner Arbeit und den notwendigen Spass bei der Arbeit.

Ich danke der Deutschen Forschungsgemeinschaft (DFG) für die finanzielle Unterstützung durch die Projekte "Experimentelle und computerbasierte Analyse der auftretenden Kräfte innerhalb hochporöser Nanopartikelschichten während kapillargetriebenen Flüssigkeitseintritts" (MA3333/10-1) und "Flachbandpotential" (MA3333/16-1), ohne die diese Arbeit nicht möglich gewesen wäre.

Ein großes Dankeschön an meine Familie und Freunde, ganz besonders an Emilia, für notwendige Unterstützung und Motivation um diese Arbeit abzuschließen. Danke!

R_0	Initial particle radius (moving boundary)	nm
$\text{Re}(Z)$	Real part of impedance	Ω
S	Scattering Kubelka-Munk coefficient	—
S_A	Electrode surface area	cm^2
$S_{A,\text{El}}$	Electrode surface area of substrate	cm^2
$S_{A,\text{NP}}$	Electrode surface area of nanoparticles	cm^2
S_{EPR}	Electron spin	—
S_r	Surface recombination velocity	cm s^{-1}
SSA	Specific surface area	$\text{m}^2 \text{ g}^{-2}$
T	Temperature	$^\circ\text{C}$ or K
U	Potential	V
$U_{\text{Ag/AgCl}}$	Potential vs. Ag/AgCl reference electrode	V
$U_{\text{Ag/AgCl}^0}$	Potential difference between Ag/AgCl reference electrode and NHE	V
U_{App}	Applied electrode potential	V
U_{FB}	Flat band potential	V
U_H	Potential drop across Helmholtz layer	V
U_{RHE}	Potential vs. RHE	V
V_p	Total nanoparticle volume per unit liter	$\text{nm}^3 \text{ l}^{-1}$
V_0	Initial nanoparticle volume per unit liter	$\text{nm}^3 \text{ l}^{-1}$
$W(\psi, \omega)$	Transformation (a-SC)	V
$W_S(\psi, \omega)$	Surface transformation (a-SC)	V

Symbol	Description	Unit
Z	Impedance	Ω
$Z_{\text{NP-FTO}}$	Impedance at nanoparticle-FTO interface	Ω
Z_{SC}	Impedance of the space charge layer	Ω
a	Stoichiometric coefficient of species a	—
a_p	Surface area of one nanoparticle	nm^2
a_C	Atomic share of carbon (from EDX spectra)	—
a_{Ti}	Atomic share of titanium (from EDX spectra)	—
a_W	Atomic share of tungsten (from EDX spectra)	—
a_i	activity of species i	—
b	Stoichiometric coefficient of species b	—
c_{AA}	Amino acid concentration	mM
$c_{\text{AA},0}$	Initial amino acid concentration	mM
c_{BET}	BET constant	—
c_{CuO}	CuO concentration	mM
$c_{\text{CuO},0}$	Initial CuO concentration	mM
$c_{\text{Cu}^{2+}}$	Cu^{2+} concentration	mM
$c_{\text{Cu}^{2+},0}$	Initial Cu^{2+} concentration	mM
c_{Cu}	Copper concentration	$\# \text{ nm}^{-3}$
$c_{\text{Cu},0}$	Initial copper concentration	$\# \text{ nm}^{-3}$
$c_{\text{Cu},s}$	Copper surface concentration	$\# \text{ l}^{-1}$
c_{Fe}	Iron concentration	$\# \text{ nm}^{-3}$
$c_{\text{Fe},s}$	Iron surface concentration	$\# \text{ l}^{-1}$
c_{L}	Glycine concentration	M
c_{Me}	Metal concentration (Me = Ti, W, Zn, Cu)	M
c_{SC}	Specific space charge capacitance	$\text{F } \mu\text{m}^{-1}$
c_{CuCl_2}	Molar CuCl_2 concentration	M
c_i	Molar concentration of species i	M
c_p	Volumetric number density	$\# \text{ nm}^{-3}$
d	Differential operator	—
d_{BET}	BET diameter	nm
$d_{\text{p},0}$	Initial particle diameter	nm

Symbol	Description	Unit
$d_{\text{Fe,s}=1}$	Particle diameter with surface iron-copper ratio of 1	nm
e^-	Electron	—
f_{Cu}	Copper-iron ratio	—
$f_{\text{Cu},0}$	Initial copper-iron ratio	—
$f_{\text{Cu,s}}$	Surface copper-iron ratio	—
f_{Fe}	Iron-copper ratio	—
$f_{\text{Fe},0}$	Initial iron-copper ratio	—
$f_{\text{Fe,s}}$	Surface iron-copper ratio	—
f_{rot}	Revolutions per minute	# min ⁻¹
$g//$	EPR parameter	—
h	Plank constant	eV s
h^+	Hole	—
i	Index	—
j	Imaginary unit	—
j_0	Current density	mA cm ⁻²
j_E	Current density	mA cm ⁻²
k_B	Boltzmann constant	8.617 × 10 ⁻⁵ eV K ⁻¹
$k_{\text{ads/des}}$	Rate of adsorption/desorption	a.u.
k_{Cu}	Copper release rate constant	h ⁻¹ mM ^{-2.75}
$k_{\#,s} = k_{\#,v} \Delta s$	Copper concentration per unit surface area	# nm ⁻²
$k_{\#,v} = \frac{\rho_{\text{CuO}} N_A}{M_{\text{CuO}}}$	Volumetric number density of copper atoms	# nm ⁻³
l	Thickness of cuvette	mm
m_λ	Slope of linear regression	nm mM ⁻¹
m^*	Effective mass	g
m_i	Initial mass of particle	g
$m_D(t)$	Dissolved mass of particle	g
$m_P(t)$	Remaining mass of particle	g
m	Partial reaction order (c_{CuO}^m)	—
n	Partial reaction order (c_{AA}^n)	—
n_{cycles}	Number of cycles in CV	—
n_C	Number of carbon atoms	—
n_{Cu}	Volumetric copper concentration	# nm ⁻³
$n_{\text{Cu},0}$	Initial volumetric copper concentration	# nm ⁻³
n_{Fe}	Volumetric iron concentration	# nm ⁻³

Symbol	Description	Unit
$n_{\text{Fe},0}$	Initial volumetric iron concentration	# nm ⁻³
n_T	Exponential factor Kubelka-Munk transformation	—
p	Pressure	N cm ⁻²
p_0	Atmospheric pressure	N cm ⁻²
pH	Negative decadic logarithm of OH ⁻ ion concentration	—
q	Elementary charge	1.602×10^{-19} C
$r(t)$	Nanoparticle radius	nm
r_0	Initial nanoparticle radius	nm
r_{CT}	Nanoparticle-electrolyte resistance per unit length	$\Omega \mu\text{m}^{-1}$
r_{NP}	Internal nanoparticle resistance per unit length	$\Omega \mu\text{m}^{-1}$
r_s	Adsorption ratio MO/MGO	—
$r_{\infty,\text{mod}}$	Final particle radius, model	nm
$r_{\infty,\text{theo}}$	Final particle radius, theoretical	nm
t	Time	s, min, h
v	Volume	nm ³
v_m	Volume monolayer (BET)	nm ³
v_p	Volume of one nanoparticle	nm ³
$v_{p,0}$	Initial volume of one nanoparticle	nm ³
x	Coordinate	nm
y	Coordinate	nm
z	Number of electrons involved in reaction	#
z_{Me}	Number of metal atoms in a phase	#
